Hash tables map keys to buckets using a hash function.

Stacks follow the last in, first out principle.

Breadth first search uses a queue to explore nodes level by level.

CSC 201 — Data Structures

A stack overflow occurs when the call stack exceeds its limit.

A linked list stores elements in nodes connected by pointers.

A binary tree has at most two children per node.

Circular queues reuse empty slots at the front of the array.

Binary search runs in logarithmic time on a sorted array.

Traversal visits every node of a tree exactly once.

Insertion at the head of a singly linked list runs in constant time.

Queues process elements in first come, first served order.
